**Quick Response Code:**

Dear Editor,

I am writing to highlight the significance of physiognomy as an initial assessment tool in medical practice. Physiognomy, the study of facial features to infer aspects of character and health, has historically been viewed with skepticism. However, its potential utility in modern medicine warrants renewed consideration, particularly for its role in enhancing initial patient assessments.<sup>[1]</sup>

Physiognomy has ancient roots, with references dating back to Aristotle, who suggested that facial features could reveal insights into a person's character. Cesare Lombroso, a 19<sup>th</sup> century Italian physician and criminologist, further developed this concept. Lombroso's work attempted to correlate facial characteristics with criminal behavior, asserting that the face could reveal predispositions to certain behaviors and mental states. While Lombroso's theories have been largely discredited in the context of criminal anthropology, the foundational idea that facial expressions and features can reflect psychological and physiological states remains relevant.<sup>[2]</sup>

In contemporary medical practice, physicians often unconsciously use principles of physiognomy during initial patient interactions. Observations of facial expressions, skin tone, and muscle tension can provide immediate, although preliminary, insights into a patient's emotional and physical state. For example, deep lines on the forehead may indicate chronic stress, while a pale complexion could suggest anemia or other systemic issues. Such initial impressions can guide further questioning and diagnostic testing, potentially leading to earlier and more accurate diagnoses.<sup>[3,4]</sup>

The integration of physiognomy into initial medical assessments offers several advantages. First, it provides rapid, non-invasive insights that can complement traditional diagnostic methods. This can be particularly valuable in settings where time and resources are limited. For instance, a patient presenting with visible signs of anxiety or distress may be experiencing underlying psychological conditions that could affect their overall health and response to treatment. Recognizing these signs early allows for a more holistic approach to patient care.<sup>[5,6]</sup>

Second, the use of physiognomy can enhance the patient-doctor relationship. Physicians can demonstrate empathy and understanding by paying close attention to non-verbal cues, fostering trust and open communication. This is particularly important in cases where patients may

have difficulty articulating their symptoms or concerns. An empathetic approach that considers both verbal and non-verbal communication can improve patient satisfaction and adherence to treatment plans.<sup>[7,8]</sup>

Despite its potential benefits, physiognomy must be approached with caution in medical practice. It is essential to avoid overreliance on subjective interpretations and ensure that observations are corroborated with objective diagnostic tests. Furthermore, training in physiognomy should be incorporated into medical education to ensure that health-care professionals can accurately and ethically interpret facial cues.

Recent advancements in technology offer promising opportunities for applying physiognomy in medicine. Artificial intelligence<sup>[9]</sup> and machine learning algorithms can be trained to analyze facial expressions and features, potentially identifying subtle cues that may be overlooked by the human eye. These tools could augment the physician's observational skills, providing additional data points for a more comprehensive assessment.<sup>[10]</sup>

In conclusion, as an initial assessment tool, physiognomy offers a complementary approach that can enrich the diagnostic process in medical practice. By integrating observations of facial features with traditional diagnostic methods, physicians can gain a more holistic understanding of their patients' health. Further research and training in this field could enhance its application, ultimately improving patient outcomes. I encourage the medical community to consider physiognomy's potential and explore its integration into clinical practice through rigorous research and ethical implementation.

## ETHICAL APPROVAL

Institutional Review Board approval is not required.

## DECLARATION OF PATIENT CONSENT

Patient's consent is not required as there are no patients in this study.

## USE OF ARTIFICIAL INTELLIGENCE (AI)-ASSISTED TECHNOLOGY FOR MANUSCRIPT PREPARATION

The author confirms that no artificial intelligence (AI)-assisted technology was used to assist in the writing or editing of the manuscript, and no images were manipulated using AI.

## CONFLICTS OF INTEREST

There are no conflicting relationships or activities.

## FINANCIAL SUPPORT AND SPONSORSHIP

This study did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.
